In assessing wildfire risks and severity, much of the existing literature is sourced from a mainstream, euro-centric perspective that places emphasis on maintaining human development and settlements, regardless of the existing ecosystems. Incorporating indigenous knowledge not only fills in some of the current knowledge gaps but also reframes the perspectives around how wildland fire is viewed – good or bad, beneficial or detrimental. The addition of indigenous knowledges highlights how fire can be a form of fire management which can in turn reduce the overall severity of wildland fires, as well as the frequency of severe wildland fires, especially those that threaten communities living on the edge of the wildland-urban interface (WUI). Incorporating indigenous data and knowledge has the very likely potential to adjust our firefighting and fire management practices, something that will be increasingly improvement as weather patterns continue to support more dramatic fire conditions and seasons.
